ABSTRACT

In chemical engineering field, there are many processes which need to optimize more than one responses, called multi-response, simultaneously. In this study, it is aimed to analyse the effects of operating parameters (modeling) and to obtain the compromise process factor values (optimization) for a continuous saponification process. The novelty of this study is considering the saponification process as a multi-response problem. It is important both engineering and statistical aspects. For the continuous saponification process, sodium hydroxide (X1), ethyl acetate concentrations (X2), and their volumetric flow rates (X3, X4) were regarded as the process factors in order to maximize the conversion of sodium hydroxide (Y1) and to minimize the space time (Y2) which is calculated analytically by using X3 and X4. Response Surface Methodology (RSM) and Desirability Function Approach (DFA) were used for modeling and optimization of the process, respectively. Therefore, it is clear that compromise factor conditions which are obtained by the optimization of conversion and space time simultaneously will satisfy the product quality and process economy.

Keywords: saponification process, response surface methodology (rsm), desirability function, optimization

İstenebilirlik fonksiyonu yaklaşımı kullanarak çok yanılış çıkarılmış sabunlaşma süreçinin optimizasyonu

1. INTRODUCTION

A reaction of an ester with sodium hydroxide to give a carboxylic acid salt and an alcohol is called saponification reaction, though not the final product is soap. This reaction is also known as hydrolysis of esters with base catalyst. Although water, alcohol or similar solvents can not solve esters, product of the saponification reaction is definitely soluble in all these solvents. This property is important in view of the usage area of carboxylic acid salt obtained at the end of the saponification reaction. Sodium acetate is a commercially important carboxylic acid salt which is used in a large area in industry such as petroleum, cosmetic, textile, paint, food etc. In addition to the commercial importance, the saponification reaction is often preferred in both education and research purposes as a model reaction. In the study of Simandi et al. (1996), a mixing model with non-ideal mixing using saponification reaction is presented. A dynamic model based on the pseudo bond graph technique is developed by Heny et al. (2000) to represent the behavior of a continuous stirred tank reactor (CSTR) for the saponification of ethyl acetate with sodium hydroxide. A new method for the determination of rate constant is presented by Krupska et al. (2002). In chemical engineering education, this second order reaction is used to understand the kinetic analysis and reactor performance [4].

Response Surface Methodology (RSM) is used in many chemical engineering applications. RSM is used as a useful tool for optimization in analytical chemistry by Bezerra et al. (2008). In the studies of Chi et al. (2012) and Istadi (2005), multi-response optimization (MRO) is interested in RSM framework about catalytic epoxidation process and carbon dioxide oxidative coupling of methane, respectively. Desirability function approach (DFA) is used for MRO of nickel electroplating process by Seritan et al. (2011). Salimon et al. (2012) and Bursali et al. (2006) used D-optimal design and RSM for saponification reaction, respectively.

In this study, it is aimed to model a continuous saponification process and to obtain the optimal values of operating parameters. The RSM and the DFA are used for modeling and optimization stages of saponification process, respectively. It is seen from the statistical analysis that the obtained compromise operating parameter values satisfy the product quality and process economy simultaneously.

2. RESPONSE SURFACE METHODOLOGY AND LINEAR MULTI-RESPONSE MODEL

Response Surface Methodology (RSM) is a collection of statistical and mathematical techniques applied to obtain a proper functional relationship between a response of interest and a number of associated factors (input or independent variables) [11]. A complete and detailed explanation about RSM is referred to [12-14]. In the field of RSM, there are three main stages: (i) designing a set of experiments, (ii) determining a mathematical model, and (iii) determining the optimal settings of factors. An experiment can involve several response (dependent) variables, which is called multi-response experiment, as well as single response variable. If a multi-response experiment is designed, which means that the factors are selected and their values during the actual experimentation are designated, the task then is to find a proper approximation for the true functional relationship between the factors and unknown response surfaces. Regression analysis helps to form the relationship between response variables and factors denoted by \( (Y_1, Y_2, ..., Y_r) \) and \( (X_1, X_2, ..., X_k) \), respectively. In general, such a relationship is unknown. In order to model an unknown response \( (Y) \), first and second degree polynomial regression models, given in Eq.(1) and Eq.(2), are used.

\[
Y = \beta_0 + \sum_{i=1}^{k} \beta_i X_i + \varepsilon \tag{1}
\]

\[
Y = \beta_0 + \sum_{i=1}^{k} \beta_i X_i + \sum_{i=4}^{k} \beta_{ij} X_i^2 + \sum_{i=1}^{k} \beta_{ij} X_i X_j + \varepsilon \tag{2}
\]

Here, \( \beta_0 \) is constant, \( \varepsilon \) is error term, \( (X_1, X_2, ..., X_k) \) is linear terms vector, \( (X_1^2, X_2^2, ..., X_k^2) \) is squared terms vector, \( (X_1 X_2, X_1 X_3, ..., X_{k-1} X_k) \) is first interaction terms vector of each paired combination, and \( \beta_i, \beta_{ij}, \beta_{ij} \), \( i = j = 1, 2, ..., k \) are unknown model coefficients.

The data analysis of multi-response experiments need a careful consideration. In the design of multi-response experiment, design criterion should be based on perceiving the responses as a group rather than as individual entities [12]. The correlation structure of the response variables should be considered during the modeling stage. In this case, simultaneous modeling of unknown responses as a function of the input variables is necessary within some region of interest. The model associated with such a function is called multi-response model.
A multi-response model is composed of $r$ number of polynomial regression models which are considered as an approximation function of each unknown responses. In this case, the $i$'th response model can be written in a vector form as

$$Y_i = X_i \beta_i + \varepsilon_i, \quad i = 1, 2, ..., r$$

where $Y_i$ is a $n \times 1$ vector of observations (experimental runs for each setting of a group of $k$ coded variables), $X_i$ is a $n \times p_i$ matrix of rank $p_i$ of known functions of the settings of the coded variables, $\beta_i$ is a $p_i \times 1$ vector of unknown constant parameters, and $\varepsilon_i$ is a random error vector associated with the $i$'th response ($i=1, 2, ..., r$). Here, it is assumed that

$$E(\varepsilon_i) = 0, \quad Var(\varepsilon_i) = \sigma^2_i I_n, \quad i = 1, 2, ..., r$$

$$Cov(\varepsilon_i, \varepsilon_j) = \sigma^2_i I_n, \quad i, j = 1, 2, ..., r; \quad i \neq j$$

and also the $r \times r$ matrix whose $(i, j)$th element is $\sigma^2_{ij}, \quad (i, j=1, 2, ..., r)$ will be denoted by $\Sigma$. The $r$ equations given in Eq. (3) may be represented as

$$Y = X\beta + \varepsilon$$

where $X$ is the block-diagonal matrix, $X = \text{diag}(X_1, X_2, ..., X_r);$  $Y = [Y_1' : Y_2' : ... : Y_r']'$, $\beta = [\beta_1' : \beta_2' : ... : \beta_r']'$, and $\varepsilon = [\varepsilon_1' : \varepsilon_2' : ... : \varepsilon_r']'$ are vectors with dimensions $nr \times 1$, $p \times 1$, and $nr \times 1$, respectively. The best linear unbiased estimator (BLUE) of $\beta$ is given by

$$\hat{\beta} = (X'\Delta^{-1}X)^{-1}X'\Delta^{-1}Y$$

where $\Delta = \Sigma \otimes I_n$ and $\otimes$ is a symbol for the Kronecker product of matrices, hence $\Delta^{-1} = \Sigma^{-1} \otimes I_n$. The estimator given in Eq. (6) is called Generalized Least Square Estimator (GLME). The GLME of $\beta$ requires knowledge of $\Sigma$. If $\Sigma$ is unknown, then an estimate of $\beta$ can be obtained by replacing $\Sigma$ by an estimate $\hat{\Sigma}$ provided that the estimate is nonsingular. Zellner [15] proposed an estimate such as $\hat{\Sigma} = (\hat{\sigma}_{ij})$, $i, j = 1, 2, ..., r$ where

$$\hat{\sigma}_{ij} = \frac{Y_i'(I_n - X_i(X_i'X_i)^{-1}X_i')Y_j}{n}.$$
The individual desirability function for the case of Eq. (10) has values inside the interval [0,1] and approaches unity as the desirability of the responses increases. The geometric mean is chosen as an objective function because it vanishes whenever any $d_i, i=1,2,...,r$ is equal to zero, that is, if at least one of the response variables is unacceptable [12]. Harrington’s approach is extended by Derringer and Suich (1980) by offering systematic transformations to desirability function. In addition, a new form of overall desirability by using a weighted geometric mean suggested by Derringer (1994) as

$$D = \left( d_1^{w_1} \times d_2^{w_2} \times \ldots \times d_r^{w_r} \right)^{1/w} \quad (11)$$

where the $w_i, i=1,2,...,r$ are the weights among the response. If all the $w_i$'s are set to 1, Eq. (11) reduces to Eq. (10).

The individual desirability function for the case of minimization and maximization of a response is defined, respectively, as

$$d_i(\hat{Y}_i(X)) = \begin{cases} 
1, & \hat{Y}_i(X) \leq Y_i^{\min} \\
\frac{(Y_i^{\max} - \hat{Y}_i(X))^{s}}{Y_i^{\max} - Y_i^{\min}}, & Y_i^{\min} < \hat{Y}_i(X) \leq Y_i^{\max}, i = 1, ..., r \\
0, & \hat{Y}_i(X) > Y_i^{\max} 
\end{cases} \quad (12)$$

where $d_i(\hat{Y}_i(X)), i = 1,2,...,r$ is the desirability function of $\hat{Y}_i(X)$. $s$ is the parameter that define the shape of desirability functions. In this study, $s = 1$ is chosen which denotes linear transformation. $Y_i^{\min}$ and $Y_i^{\max}$ can be set at the extreme values of the individual predicted responses as $Y_i^{\min} = \min_{X \in S} \{\hat{Y}_i(X)\}$ and $Y_i^{\max} = \max_{X \in S} \{\hat{Y}_i(X)\}$ which represent the minimum and maximum possible values of the predicted response within the experimental region $S$, respectively. The proposed desirability functions given in (12) and (13) transform the each response to a corresponding desirability value between 0 and 1. The optimization process is relatively simple since the overall desirability is a well-behaved continuous function of the factors.

4. **APPLICATION**

4.1. **Problem Definition**

In this study, a continuous saponification process was carried out as a multi-response problem. The saponification reaction between ethyl acetate (EtOAc, CH$_3$COOC$_2$H$_5$) and sodium hydroxide (NaOH) can be represented by the following stochiometric equation:

$$\text{NaOH} + \text{CH}_3\text{COOC}_2\text{H}_5 \rightarrow \text{CH}_3\text{COONa} + \text{C}_2\text{H}_5\text{OH} \quad (14)$$

As the reaction proceeds consumption of hydroxide ions results in the formation of acetate ions. Since the hydroxide ions have much larger specific conductance than the acetate ions, sodium hydroxide concentration can be monitored by measuring the conductivity of the reaction mixture. The continuous operation concentrations of the reactants in the feed flow can be calculated as given in Eqs. (15)-(16) where $C_{\text{do}}$ and $C_{\text{bo}}$ are the concentrations of sodium hydroxide and ethyl acetate, respectively. The $Q_\text{f}$ and $Q_\text{b}$ represent the volumetric feed flow rates of sodium hydroxide and ethyl acetate. Reservoir concentrations of sodium hydroxide and ethyl acetate were represented as $C_{\text{s,1}}$ and $C_{\text{s,2}}$, respectively
Optimization of saponification process in multi-response framework by using desirability function approach

\[ C_{do} = \frac{Q_A}{Q_A + Q_B} C_{int1} \]  
\[ (15) \]

and

\[ C_{bo} = \frac{Q_A}{Q_A + Q_B} C_{int2}. \]  
\[ (16) \]

Concentration of sodium hydroxide during the course of the reaction is calculated by using Eq. (17) from the conductivity measurements of the reaction mixture [28]. Conversion of sodium hydroxide (\( x_A \)) is calculated for each continuous operation by using the Eq. (18) for the steady state value of \( C_A \)

\[ C_A = (C_{do} - C_{bo}) \left[ \frac{K_D}{K_D - K} \right] + C_{do} \]  
\[ (17) \]

and

\[ x_A = \frac{C_{do} - C_A}{C_{do}} \]  
\[ (18) \]

In order order to model the process, \( C_{do}, C_{bo}, Q_A, \) and \( Q_B \) were considered as factors denoted with \( X_1, X_2, X_3, \) and \( X_4 \), respectively. The first response variable (\( Y_1 \)) was chosen \( x_A \) and the space time was considered as second response (\( Y_2 \)) given in Eq. (19)

\[ \tau = \frac{V}{Q_A + Q_B} \]  
\[ (19) \]

The experimental system used in the study is given in Fig. 1. A 2 L bench-top reactor (Armfield CEM-Liquid Phase Chemical Reactor, England) with temperature and agitation rate control units was used. Reactants (sodium hydroxide and ethyl acetate) were fed at constant rates by using computer controlled pumps into the reactor. The conductivity measurements of the reaction mixture were done by using WTW LF39 (Welheim, Germany) type conductivity meter. Temperature and agitation rate were kept at the values of 25°C and 250 rpm in all experiments, respectively, since these were found as insignificant operating parameters at their selected ranges from previous study [10].

4.2. Data Set

A series of experiments were carried out in order to examine the saponification process. The purpose of the experiments was to determine the effects of \( X_1, X_2, X_3, X_4 \) on \( Y_1 \) and \( Y_2 \), which wanted to be maximized and minimized, respectively. The experiments were conducted in 2\(^4\) Full Factorial Design. In the design, each input variable was measured at two levels which can be coded to take the value \(-1\) when the input is at its low level and \(+1\) when at its high level. The coded values and actual values of input variables were given in Table 1. In Table 2, experimental data set with four added center points were given.

4.3. Modeling and Optimization of Multi-Responses

The observed responses were checked that if there were correlations between the responses before modeling. It was seen that the responses were uncorrelated according to the correlation analysis \( p = 0.99 > \alpha = 0.05 \). Then, the experimental data set was statistically analyzed using Minitab 14 [29]. The goodness of fit of the models were evaluated by the analysis of variance (ANOVA) given in Table 3.

The obtained models for both responses were fitted as

\[
\hat{Y}_1 (X) = 0.788 - 0.0556X_1 + 0.223X_2 + 0.0531X_3 - 0.0494X_4 - 0.243X_1^2, \quad R^2 = 79\% \quad (20)
\]

\[
\hat{Y}_2 (X) = 16.6 - 10X_1 - 10X_2 + 6.70X_3^2 + 6.70X_3X_4, \quad R^2 = 100\% \quad (21)
\]

The response surface models were developed with values of \( R^2 \), 79% and 100% for \( Y_1 \) and \( Y_2 \), respectively. It is obvious from Eq. (20) that the feed concentration of ethyl acetate (\( X_2 \)) affects the conversion of sodium hydroxide (\( Y_1 \)) directly proportional whereas the feed concentration of sodium hydroxide (\( X_1 \)) affects the conversion of sodium hydroxide (\( Y_1 \)) inversely proportional. In other words, increasing sodium hydroxide concentration in the feed from 0.01 mol/L to 0.1 mol/L decreased the conversion and increasing ethyl acetate concentration in the feed from 0.01 mol/L to 0.1 mol/L increased the conversion. These results are comparable with the previous study performed in batch process [10]. If the coefficients of the first model, given in Eq. (20), are evaluated according to their absolute values it is clear that the most effective parameter is the feed concentration of ethyl acetate. It can be said that from the Eq. (21), the increment in the feed flow rates of sodium hydroxide and ethyl acetate cause to decrease in the space time. This result reflects the hydraulic behavior of the continuous stirred tank reactor. The obtained individual optimization results of the predicted response functions are \( \hat{Y}_1^* = 1 \), \( X^* = [-0.1365 \ 0.8664 \ 0.1587 \ -0.1476] \) and \( \hat{Y}_2^* = 6.1937 \), \( X^* = [0.2463 \ 1] \). The contour plots of predicted response functions, given in Eq. (20) and Eq. (21), are shown in Fig. 2 and Fig. 3 by using Matlab 7.9 [30], respectively.

Figure 2. Predicted response surface plot of \( Y_1 \) as a function of \( X_1 \) and \( X_2 \) in which the \( X_3 = 0.1587 \) and \( X_4 = -0.1476 \) are kept their optimal values obtained by the individual maximization of \( Y_i \)

Figure 3. Predicted response surface plot of \( Y_2 \) as a function of \( X_3 \) and \( X_4 \)
The aim of the study is to get maximum value of the 
\( \hat{Y}_1(X) \) and minimum value of the \( \hat{Y}_2(X) \). Therefore, the MRO problem can be written as

\[
\begin{align*}
\text{max } & \hat{Y}_1(X) \\
\text{min } & \hat{Y}_2(X) \\
0.1639 & \leq \hat{Y}_1(X) \leq 1 \\
6.1937 & \leq \hat{Y}_2(X) \leq 50 \\
X & \in \mathcal{S}
\end{align*}
\]  \tag{22}

where \( \mathcal{S} \in [-1, 1] \). In (22), the lower and the upper bounds of the predicted responses, \( \hat{Y}_1(X) \) and \( \hat{Y}_2(X) \), are calculated as the individual minimum and maximum values of each responses. Afterwards, the individual desirability functions for the responses can be defined as

\[
d_i(\hat{Y}_i(X)) = \left\{ \begin{array}{ll}
1 & , \quad \hat{Y}_i(X) \geq 1 \\
\frac{(\hat{Y}_i(X) - 0.1639)}{1 - 0.1639} & , \quad 0.1639 \leq \hat{Y}_i(X) < 1 \\
0 & , \quad \hat{Y}_i(X) < 0.1639
\end{array} \right.
\]  \tag{23}

and

\[
d_i(\hat{Y}_2(X)) = \left\{ \begin{array}{ll}
1 & , \quad \hat{Y}_2(X) \leq 6.1937 \\
\left(\frac{50 - \hat{Y}_2(X)}{50 - 6.1937}\right)^{2} & , \quad 6.1937 \leq \hat{Y}_2(X) \leq 50 \\
0 & , \quad \hat{Y}_2(X) > 50.
\end{array} \right.
\]  \tag{24}

The formulation of overall desirability function which wanted to be maximized can be written as

\[
\text{max } D(X) = (d_1(X) \times d_2(X))^{1/2}
\]  \tag{25}

The optimal input vector values of the \( D(X) \), defined by Eq.(25), is \( X' = [-0.1137 \ 0.4564 \ 1] \) with the overall desirability value \( D' = 1 = 99\% \). The individual predicted response values are calculated as \( \hat{Y}_1' = 0.989 \) and \( \hat{Y}_2' = 6.4895 \text{ min}^{-1} \) by using the DFA factor conditions.

5. CONCLUSION

The objective of this study was to optimize the operating conditions of the continuous saponification process with respect to both conversion and space time. The maximization of conversion (\( x_c \)) and the minimization of space time (\( \tau \)) are important from the point of process economy and yield. Therefore, the saponification process can be considered as a multi-response problem in which the responses are uncorrelated. Investigation of the multi-response problem were performed in three steps: (i) data gathering, (ii) modeling, and (iii) optimization. At the first step, the process factors were selected as \( C_{so} \) (concentration of sodium hydroxide), \( C_{ea} \) (concentration of ethyl acetate), \( Q_s \) (feed flow rate of sodium hydroxide), and \( Q_a \) (feed flow rate of ethyl acetate). Temperature and agitation rate were not considered as factors in this study since the experiments were performed at their optimal values which were given in [10]. 2\textsuperscript{4} Full Factorial Design was used for the experiments with four center points. At the second step, second order polynomial response surface models were identified by using least square analysis. The analytical functions were calculated in Minitab 14. The validation of predicted models was confirmed by using ANOVA. It was seen that the first predicted response function was related to main effects of all factors and quadratic effect of \( C_{so} \). On the other hand, it was concluded that the second predicted response function was only related with \( Q_s \) and \( Q_a \). At the final step, DFA was used for MRO since the interested responses are uncorrelated. In order to apply DFA, individual optimal values of predicted responses were needed to determine the constraints. By considering the physical meaning of the responses, individual operating conditions were obtained. The MRO problem denoted by Eq. (22) was converted to the single objective optimization problem given in Eq. (25) by using DFA. It is seen from the optimization results that the obtained process factor levels, \( X' = [-0.1137 \ 0.4564 \ 1] \), make the conversion maximum and the space time minimum as 0.989 and 6.4895 \text{ min}^{-1}, respectively. These response values are satisfactory in the view of process economy and yield. It can be said that simultaneous optimization is more realistic for multi-response saponification process in the case of feasibility.
